

ROTATION SHAFT SUPPORT STRUCTURE OF MOTOR

Background of the Invention

1. Field of the Invention

The present invention relates to a rotation shaft support structure of a motor, and more particularly to a rotation shaft support structure of a motor, wherein the rotation shaft of a rotor of the motor has an end face rested on a support member, so that the rotor may form a stable rotation.

2. Description of the Related Art

U.S. Pat No. 6,290,471, issued on Sep. 18, 2001 to Horng, entitled by "Pivotal Structure for an Impeller of a Miniature Heat Dissipating Fan", comprises a casing provided with a shaft tube, a stator coil seat, a circuit board, and a balance plate. The shaft tube is provided with one or two bearings. The shaft of the impeller is pivoted in the shaft hole of the bearing. The end face of the shaft is rested on the closure member of the shaft tube. The annular magnet of the impeller may be induced with the stator coil seat and may attract the balance plate, so that the impeller may be rotated along a fixed track.

If the closure member of the shaft tube is made of metallic material, the closure member and the shaft tube may have a better combination. However, when the end face of the shaft of the impeller is rested on the closure member to rotate, friction noise is produced. If the closure member of the shaft tube is made of non-metallic material, when the end face of the shaft of the impeller is rested on the closure member to rotate, the friction noise may be reduced. However, the closure member made of non-metallic material cannot be combined with the shaft tube securely.

Summary of the Invention

The primary objective of the present invention is to provide a rotation shaft support structure of a motor, wherein the rotation shaft of a rotor

Fig. 6 is a front plan cross-sectional assembly view of a rotation shaft support structure of a motor in accordance with a fourth embodiment of the present invention.

Detailed Description of the Preferred Embodiments

Referring to the drawings and initially to Fig. 1, a rotation shaft support structure of a motor in accordance with a first embodiment of the present invention comprises a shaft tube 1, a seal member 2, and a support member 3.

The shaft tube 1 may be a conventional metallic tube. At least one bearing 11 is placed in the shaft tube 1, for supporting a rotation shaft 10 of a rotor to rotate. A snapping member 12 is snapped on the rotation shaft 10 of the rotor, thereby preventing detachment of the rotation shaft 10 of the rotor. The shaft tube 1 has one end face combined with the seal member 2.

The seal member 2 is made of metallic material. Thus, the seal member 2 and the shaft tube 1 may be securely combined in a close fit manner. The seal member 2 may be provided with a recess 21 which has a periphery formed with an annular wall 22.

The support member 3 is made of a wear resistant non-metallic material. The support member 3 has a resting portion 31 on which the end face of the rotation shaft 10 of the rotor may be rested. In the preferred embodiment of the present invention, the area of the resting portion 31 of the support member 3 is slightly smaller than that of the recess 21 of the seal member 2. The resting portion 31 of the support member 3 has a periphery provided with multiple separable plates 32. Thus, the multiple separable plates 32 of the support member 3 may be bent and may be supported in the inner wall of the recess 21 of the seal member 2, so that the resting portion 31 of the support member 3 may be placed and positioned in the recess 21 of the seal member 2.

Referring to Fig. 2, the shaft tube 1 has one end combined with the seal member 2. The seal member 2 is made of metallic material. Thus, the seal member 2 and the shaft tube 1 may be securely combined in a close fit manner. The support member 3 may be placed in the recess 21 of the seal member 2, and the multiple separable plates 32 of the support member 3 may be bent and may be securely rested on the inner wall of the recess 21 of the seal member 2, so that the support member 3 may be rigidly positioned in the shaft tube 1 by resting of the seal member 2, and may be rested on one end of the rotation shaft 10. The area circled by the multiple separable plates 32 of the support member 3 is slightly greater than the outer diameter of the rotation shaft 10. The outer wall of the rotation shaft 10 is provided with the bearing 11 which may support the rotation shaft 10 to rotate. Further, the support member 3 is made of a wear resistant non-metallic material. Thus, the rotation shaft 10 rested on the resting portion 31 of the support member 3 may have a more smooth rotation. In addition, the noise of friction produced between the rotation shaft 10 and the resting portion 31 of the support member 3 during rotation of the rotation shaft 10 may be reduced to the minimum.

Ans. 7
~~Referring to Fig. 3, a rotation shaft support structure of a motor in accordance with a second embodiment of the present invention comprises a shaft tube 1, a seal member 2, and a support member 4.~~

At least one bearing 11 is mounted in the inner wall of the shaft tube 1, for supporting a rotation shaft 10 of a rotor to rotate. A snapping member 12 is snapped on the rotation shaft 10 of the rotor, thereby preventing detachment of the rotation shaft 10 of the rotor. The shaft tube 1 has one end combined with the seal member 2. The seal member 2 is made of metallic material. The seal member 2 may be provided with a recess 21 for placing the support member 4. The recess 21 has a periphery formed with an annular wall 22.

Ins-
23

1 ~~The support member 4 is made of a wear resistant non-metallic~~
2 material. The support member 4 is placed in the recess 21 of the seal member 2.
3 The support member 4 is formed with a cup-shape or a bowl-shape. The
4 bottom of the support member 4 may be formed with a resting portion 41. The
5 resting portion 41 of the support member 4 has a periphery provided with an
6 annular wall 42. The area circled by the annular wall 42 of the support member
7 ~~4 is slightly greater than the outer diameter of the rotation shaft 10.~~

8 Referring to Fig. 4, the rotation shaft support structure of a motor in
9 accordance with a second embodiment of the present invention is assembled.
10 At least one bearing 11 is mounted in the inner wall of the shaft tube 1 which
11 has one end combined with the seal member 2 that is made of metallic material.
12 Thus, the seal member 2 and the shaft tube 1 may be securely combined in a
13 close fit manner. The support member 4 may be placed in the recess 21 of the
14 seal member 2. The rotation shaft 10 is passed through the bearing 11, and one
15 end of the rotation shaft 10 is rested on the resting portion 41 of the support
16 member 4. Thus, the rotation shaft 10 may have a stable rotation. In addition,
17 the support member 4 is made of a wear resistant non-metallic material. Thus,
18 the noise of friction produced between the rotation shaft 10 and the resting
19 portion 41 of the support member 4 during rotation of the rotation shaft 10 may
20 be reduced to the minimum.

21 Referring to Fig. 5, a rotation shaft support structure of a motor in
22 accordance with a third embodiment of the present invention is assembled. At
23 least one bearing 11 is mounted in the inner wall of the shaft tube 1 which has
24 one end combined with the seal member 2 that is made of metallic material.
25 Thus, the seal member 2 and the shaft tube 1 may be securely and rigidly
26 combined in a close fit manner. The support member 5 is placed in the recess
27 21 of the seal member 2. The support member 5 is formed with an inverted

1 hat-shape. The support member 5 may be formed with a resting portion 51 on
2 which one end of the rotation shaft 10 of the rotor may be rested. The resting
3 portion 51 has a periphery protruded with an annular lip 52 that may be locked
4 on the annular wall 22 of the seal member 2. The rotation shaft 10 is passed
5 through the bearing 11, and one end of the rotation shaft 10 is rested on the
6 resting portion 51 of the support member 5. Thus, the rotation shaft 10 may
7 have a stable rotation. In addition, the support member 5 is made of a wear
8 resistant non-metallic material. Thus, the noise of friction produced between
9 the rotation shaft 10 and the resting portion 51 of the support member 5 during
10 rotation of the rotation shaft 10 may be reduced to the minimum.

11 Referring to Fig. 6, a rotation shaft support structure of a motor in
12 accordance with a fourth embodiment of the present invention is assembled. At
13 least one bearing 11 is mounted in the inner wall of the shaft tube 1 which has
14 one end combined with a plate-shaped seal member 6 that is made of metallic
15 material. Thus, the seal member 6 and the shaft tube 1 may be securely and
16 rigidly combined in a close fit manner. The support member 4 may be placed
17 on the seal member 6. The support member 4 is formed with a cup-shape or a
18 bowl-shape. The bottom of the support member 4 may be formed with a resting
19 portion 41. The resting portion 41 of the support member 4 has a periphery
20 provided with an annular wall 42. The area circled by the annular wall 42 of the
21 support member 4 is slightly greater than the outer diameter of the rotation
22 shaft 10. The rotation shaft 10 is passed through the bearing 11, and one end of
23 the rotation shaft 10 is rested on the resting portion 41 of the support member 4.
24 Thus, the rotation shaft 10 may have a stable rotation. In addition, the support
25 member 4 is made of a wear resistant non-metallic material. Thus, the noise of
26 friction produced between the rotation shaft 10 and the resting portion 41 of

1 the support member 4 during rotation of the rotation shaft 10 may be reduced
2 to the minimum.

3 Thus, in the rotation shaft support structure of a motor of the present
4 invention, the seal member is made of metallic material. Thus, the seal member
5 and the inner wall of the shaft tube may be securely and rigidly combined in a
6 close fit manner, and the seal member may support the support member stably
7 and rigidly. Thus, when one end of the rotation shaft is rested on the support
8 member during rotation, the rotation shaft may have a stable and rigid rotation.
9 In addition, when the rotation shaft is rotated, the noise of friction may be
10 reduced to the minimum.

11 Although the invention has been explained in relation to its preferred
12 embodiment as mentioned above, it is to be understood that many other
13 possible modifications and variations can be made without departing from the
14 scope of the present invention. It is, therefore, contemplated that the appended
15 claim or claims will cover such modifications and variations that fall within the
16 true scope of the invention.
